Programming and Data Structures with Python

Abstract data types, classes, objects

List

In Python

Repeated unit

Use only one class to represent a Node
List points to the first Node

class List:

value
next

--init--

$l = []$ ✓ For simplicity

$l = [3, 8, 7]$

$l = \text{List}()$ → --init--
sets up empty list

What does an empty list look like?

Use None

next is None - no next node

Empty list

None is the empty list

No type!

$l = \text{list}() \rightsquigarrow l = \text{None}$

Cannot say $l.append()$,
 $l.insert()$ -- .

Empty list

Singleton list

Never allow value = None anywhere else

class List:

```
def __init__(self):  
    self.value = None  
    self.next = None
```

```
def isempty(self):  
    return (self.value == None)
```

`l.isempty()`

`l.append(v)`

?

L.append(v)

node = l

while node.next != None:

node = node.next

node.next = List()

node.next.value = v

```
def append(self, v):
```

```
node = self
```

```
if self.isempty():
```

```
    self.value = v
```

```
    return
```

```
node = self # Not empty!
```

```
while node.next != None
```

```
    node = node.next
```

```
l.append(v)
```

```
node.next = List(l)
```

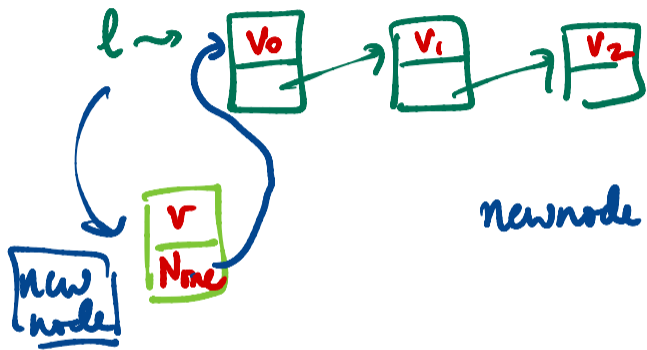

```
node.next.value = v
```

```
return
```

`l.insert(v)`

(Python's `list.insert(0, v)`)

$newnode.next = l$

$l = newnode$

All objects are mutable

Recall

def myappend(l, v):

l = l + [v]

vs

l.append(v)

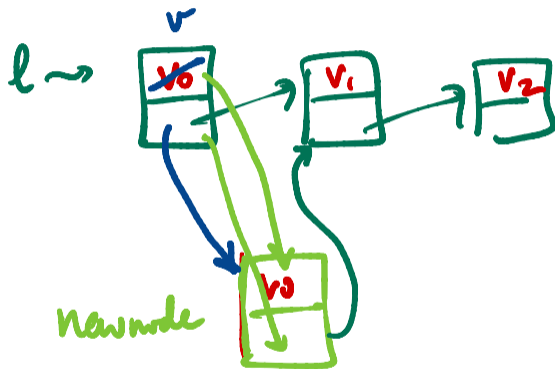

l[0]=v

newnode.next = l

l = newnode

has same problem!

Instead

```
def insert(self, v)
```

```
    if self.isempty():
```

```
        self.value = v
```

```
        return
```

```
    newnode = List()
```

```
    newnode.value = l.value
```

```
    newnode.next = l.next
```

```
    l.value = v
```

```
    l.next = newnode
```

```
    return
```

① Make `--init--` more general

`l = [3, 6, 2]`

`--init--` takes a Python list and converts it to a List

```
def --init-- (self, initlist = []):
```

```
    self.value = None  
    self.next = None
```

```
    for x in initlist:  
        self.append(x)
```

`l = []`

`l.append(3)`

`l.append(6)`

`l.append(2)`

```
def extend(self, l):  
    for x in l:  
        self.append(x)  
    return
```

Python list

```
def extend(self, l)
```

List(l)

```
if l.isempty():
```

^{return}

```
if self.isempty():
```

```
self.value = l.value
```

```
self.next = l.next
```

^{return}

```
node = self
```

```
while node.next != None:
```

```
node = node.next
```

```
node.next = l
```

```
if not (l.isempty()):
```

```
✓ node.next = l
```

```
def __str__(self):
```

Convert list()
to Python list
and do str(list)
