Queries in SQL — aggregate operations

- SQL allows arithmetic across rows
- Count the number of rows
 select count(name)
 from instructor;
- Count departments?
 - select count(dept_name)
 from instructor;
- Avoid duplicates. Instead select count(distinct dept_name) from instructor;

ID	name	dept_name	salary
10101	Srinivasan	Comp. Sci.	65000
12121	Wu	Finance	90000
15151	Mozart	Music	40000
22222	Einstein	Physics	95000
32343	El Said	History	60000
33456	Gold	Physics	87000
45565	Katz	Comp. Sci.	75000
58583	Califieri	History	62000
76543	Singh	Finance	80000
76766	Crick	Biology	72000
83821	Brandt	Comp. Sci.	92000
98345	Kim	Elec. Eng.	80000

Other functions

■ min	ID	name	dept_name	salary

	83821	Brandt	Comp. Sci.	92000
	98345	Kim	Elec, Eng.	80000

Queries in SQL — grouping

- Filter and calculate
- Extract the average value in each department
 - Group rows by department name
 - Report average in each group of rows

```
select dept_name,avg(salary)
from instructor
group by dept_name;
```

- Attributes in select must appear in group by
 - Should be the same across the entire group

ID	name	dept_name	salary
10101	Srinivasan	Comp. Sci.	65000
12121	Wu	Finance	90000
15151	Mozart	Music	40000

83821	Brandt	Comp. Sci.	92000
98345	Kim	Elec. Eng.	80000

Queries in SQL — filtering groups

- Use having to specify a condtion on groups
 - select dept_name,avg(salary)
 from instructor
 group by dept_name
 having max(salary) > 80000;
- Condition is evaluated with respect to groups

ID	name	dept_name	salary
10101	Srinivasan	Comp. Sci.	65000
12121	Wu	Finance	90000
15151	Mozart	Music	40000

```
should be empty
```

```
where dept_name = 'Comp. Sci.'
and I.salary < J.salary); ``</pre>
```

Null Values

- It is possible for tuples to have a null value, denoted by null, for some of their attributes
- null signifies an unknown value or that a value does not exist.
- The result of any arithmetic expression involving null is null
 - Example: 5 + null returns null
- The predicate is null can be used to check for null values.
 - · Example: Find all instructors whose salary is null.
 - select name from instructor where salary is null
- The predicate is not null succeeds if the value on which it is applied is not null.

Null Values (Cont.)

- SQL treats as unknown the result of any comparison involving a null value (other than predicates is null and is not null).
 - Example: 5 < null or null <> null or null = null
- The predicate in a where clause can involve Boolean operations (and, or, not); thus the definitions of the Boolean operations need to be extended to deal with the value unknown.
 - and : (true and unknown) = unknown, (false and unknown) = false, (unknown and unknown) = unknown
 - **or:** (unknown **or** true) = true, (unknown **or** false) = unknown (unknown **or** unknown) = unknown
- Result of where clause predicate is treated as *false* if it evaluates to unknown

■ Join — cartesian product combined with selection

3

イロト 不得下 イヨト イヨト

Joins in SQL

Join — cartesian product combined with selection

Joined Relations

- Join operations take two relations and return as a result another relation.
- A join operation is a Cartesian product which requires that tuples in the two relations match (under some condition). It also specifies the attributes that are present in the result of the join
- The join operations are typically used as subquery expressions in the **from** clause
- Three types of joins:
 - Natural join

Natural Join in SQL

Natural join matches tuples with the same values for all common attributes, and retains only one copy of each common column. student & courses they have then List the names of instructors along with the course to of

- the courses that they taught
 - select name, course id from students. takes where student.ID = takes.ID;
- Same guery in SQL with "natural join" construct
 - select name, course id from student natural join takes:

Natural Join in SQL (Cont.)

• The **from** clause in can have multiple relations combined using natural join:

```
select A_1, A_2, \dots, A_n
from r_1 natural join r_2 natural join ... natural join r_n
where P;
```

Student Relation

Dangerous in Natural Join

- Beware of unrelated attributes with same name which get equated incorrectly
- Example -- List the names of students instructors along with the titles of courses that they have taken
 - Correct version

select name, title
from student natural join takes, course
where takes.course_id = course.course_id;

- Incorrect version
 select name, title
 from student natural join takes natural join course;
 - This query omits all (student name, course title) pairs where the student takes a course in a department other than the student's own department.
 - The correct version (above), correctly outputs such pairs.
